

# Cautious label-wise ranking with constraint satisfaction

Sébastien Destercke, Yonatan Carlos Carranza Alarcon

DA2PL 2018

# Some announcements: SUM 2019

- When: 16-18 december 2019
- Where: Compiègne
- What: (scalable) uncertainty management
- How: papers (long/short/abstracts) but also tutorials/surveys of particular areas

# Where is Compiegne?

# Our approach in a nutshell

## What?

Cautious label-ranking by rank-wise decomposition

## How?

- Rank-wise decomposition
- For each label, predict set of ranks using imprecise probabilities
- Use CSP to:
  - resolve inconsistencies
  - remove impossible assignments

## Why?

- weak information in structured settings more prone to be of use
- few rank-wise approaches (except score-based) for this problem

# Introduction and decomposition

# Ranking data - preferences

To each instance  $x$  correspond an ordering over possible labels

## Blog theme

A blog  $x$  can be about

Politic  $\succ$  Literature  $\succ$  Movies  $\succ$  ...

## Customer preferences

A customer  $x$  may prefer

White wine  $\succ$  Red wine  $\succ$  Beer  $\succ$  ...

# Classification problem/data

$$\mathcal{C} = \{c_1, c_2, c_3\}$$

$X_1$	$X_2$	$X_3$	$X_4$	$Y$
107.1	25	<i>Blue</i>	60	$c_3$
-50	10	<i>Red</i>	40	$c_1$
200.6	30	<i>Blue</i>	58	$c_2$
107.1	5	<i>Green</i>	60	$c_4$
...	...	...	...	...

# Label ranking problem/data

$$\mathcal{W} = \{w_1, w_2, w_3\}$$

$X_1$	$X_2$	$X_3$	$X_4$	$Y$
107.1	25	<i>Blue</i>	60	$w_1 \succ w_3 \succ w_2$
-50	10	<i>Red</i>	40	$w_2 \succ w_1 \succ w_3$
200.6	30	<i>Blue</i>	58	$w_1 \succ w_2 \succ w_3$
107.1	5	<i>Green</i>	60	$w_3 \succ w_1 \succ w_2$
...	...	...	...	...

Potentially huge output space ( $K!$  with  $K$  labels)  $\rightarrow$  naive extension  
(one ranking=one class) doomed to fail

# One solution: rank-wise decomposition

$\mathbb{D}$						
$X_1$	$X_2$	$X_3$	$X_4$	$Y$		
107.1	25	<i>Blue</i>	60	$\lambda_1 \succ \lambda_3 \succ \lambda_2$		
-50	10	<i>Red</i>	40	$\lambda_2 \succ \lambda_3 \succ \lambda_1$		
200.6	30	<i>Blue</i>	58	$\lambda_2 \succ \lambda_1 \succ \lambda_3$		
107.1	5	<i>Green</i>	33	$\lambda_1 \succ \lambda_2 \succ \lambda_3$		
...	...	...	...	...		

$\mathbb{D}_1$	$\mathbb{D}_2$	$\mathbb{D}_3$

For each label, solve an ordinal regression problem

# Predicting candidate ranks

# Learning with IP: a crash course

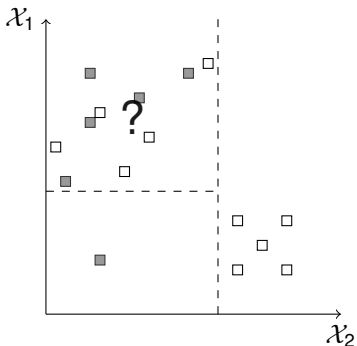

Classical case:

- input space  $\mathcal{X}$  and output space  $\mathcal{Y}$
- set  $\mathcal{D} = \{(x_1, y_1), \dots, (x_n, y_n)\}$  of data
- given  $x$ , estimate  $P(y|x)$  using  $\mathcal{D}$
- $P(y|x)$  = information about  $y$  when observing  $x$

However, estimate  $\hat{P}(y|x)$  of  $P(y|x)$  can be pretty bad if

- data are noisy, missing, imprecise
- estimation is based on little data

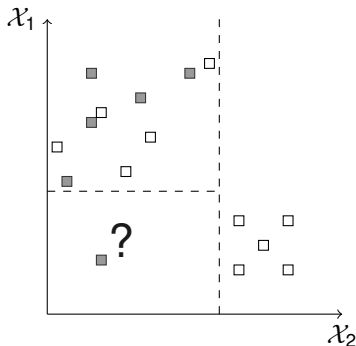

Replace the estimate  $\hat{P}(y|x)$  by **a set**  $\mathcal{P}$  of estimates

Ambiguity

$$P(\square|?) \in [0.49, 0.51]$$

$$P(\blacksquare|?) \in [0.49, 0.51]$$

Lack of information

$$P(\square|?) \in [0, 0.7]$$

$$P(\blacksquare|?) \in [0.3, 1]$$

# Decision with probability sets

## Probability sets

If  $l_\omega : \mathcal{Y} \rightarrow \mathbb{R}$  loss function of choice  $\omega \in \mathcal{Y}$ , then

$$\begin{aligned} \omega \succeq \omega' &\Leftrightarrow \inf_{P \in \mathcal{P}(y|x)} \mathbb{E}(l_{\omega'} - l_\omega) \geq 0 = \underline{\mathbb{E}}(l_{\omega'} - l_\omega) \\ &\Leftrightarrow \inf_{P \in \mathcal{P}(y|x)} \sum_{y \in \mathcal{Y}} P(y|x) (l_{\omega'}(y) - l_\omega(y)) \geq 0 \end{aligned}$$

$\Rightarrow$  if insufficient information, we can have  $\omega \not\succeq \omega'$  and  $\omega' \not\succeq \omega$

That is, we can have  $\underline{\mathbb{E}}(l_{\omega'} - l_\omega) < 0$  and  $\underline{\mathbb{E}}(l_\omega - l_{\omega'}) < 0$

$\Rightarrow$  Possibly optimal decisions = maximal element(s) of  $\succeq$

# Our choice of $\ell, \mathcal{P}$

## What?

- $\ell = L_1$  norm between ranks, loss of predicting rank  $j$  if  $k$  is true

$$\ell_j(k) = |j - k|$$

- $\mathcal{P}$  described by lower/upper cumulative distributions  $\underline{F}, \overline{F}$

## Why?

- prediction is guaranteed to be an “interval” of ranks (dedicated CSP models)
- it corresponds to the set of possible medians (very easy to get)

# An example of rank prediction

Rank $j$	1	2	3	4	5
$\bar{F}_j$	0.15	0.55	0.7	0.95	1
$\underline{F}_j$	0.1	0.3	0.45	0.8	1

Predicted rank for label:  $\{2, 3\}$

# Making a final cautious prediction

# Inconsistency and assignment reductions

## Inconsistency

Consider four labels  $\lambda_1, \lambda_2, \lambda_3, \lambda_4$ , then the predicted possible ranks

$$\hat{R}_1 = \{1, 3\}, \hat{R}_2 = \{1, 3\}, \hat{R}_3 = \{1, 3\}, \hat{R}_4 = \{2, 4\}$$

are inconsistent  $\rightarrow \lambda_1, \lambda_2, \lambda_3$  should **all** take different values

## Removal of impossible solutions

Consider the predictions

$$\hat{R}_1 = \{1, 2\}, \hat{R}_2 = \{1, 2, 3\}, \hat{R}_3 = \{2\}, \hat{R}_4 = \{1, 2, 3, 4\}.$$

As  $\lambda_3$  has to take value 2,  $\lambda_1$  has to take value  $\{1\}$ , ... until we get

$$\hat{R}'_1 = \{1\}, \hat{R}'_2 = \{3\}, \hat{R}'_3 = \{2\}, \hat{R}'_4 = \{4\}$$

# Dealing with the issue: CSP modelling

- A possible assignment  $\hat{R}_i \subseteq \{1, \dots, K\}$
- Need to find if each of them can take a different value
- Exactly what the *all different* constraint does in CSP
- So, just apply standard libraries

Bonus: if all  $\hat{R}_i$  intervals, efficient (polynomial) algorithms exist

# Experiments

# Setting

## Material and method

- Classification and regression data sets turned into ranking
- Binary decomposition + Naive imprecise classifier

## Measuring results quality

Completeness (CP)

$$CP(\hat{R}) = \frac{k^2 - \sum_{i=1}^k |\hat{R}_i|}{k^2 - k}$$

Max if one ranking possible  
Min if all rankings possible

Correctness (CR)

$$CR(\hat{R}) = 1 - \frac{\sum_{i=1}^k \min_{\hat{r}_i \in \hat{R}_i} |\hat{r}_i - r_i|}{0.5k^2}$$

Equivalent to Spearman footrule if  
one ranking predicted

# An example of results

# Why rank-wise approaches?

# Yes, why?

- different expressiveness when it comes to represent partial predictions, e.g., the set-valued prediction

$$\{\lambda_1 \succ \lambda_2 \succ \lambda_3, \lambda_2 \succ \lambda_2 \succ \lambda_1\}$$

between three labels is perfectly representable by imprecise ranks, but not through pairwise information or partial orders (i.e., interval-valued scores)

- not (entirely) clear how to make score-based methods imprecise (IP-SVM?) + need to turn them into imprecise ranks?
